

Image Processing in Python

Section 6

Created by: Rehab Mohamed

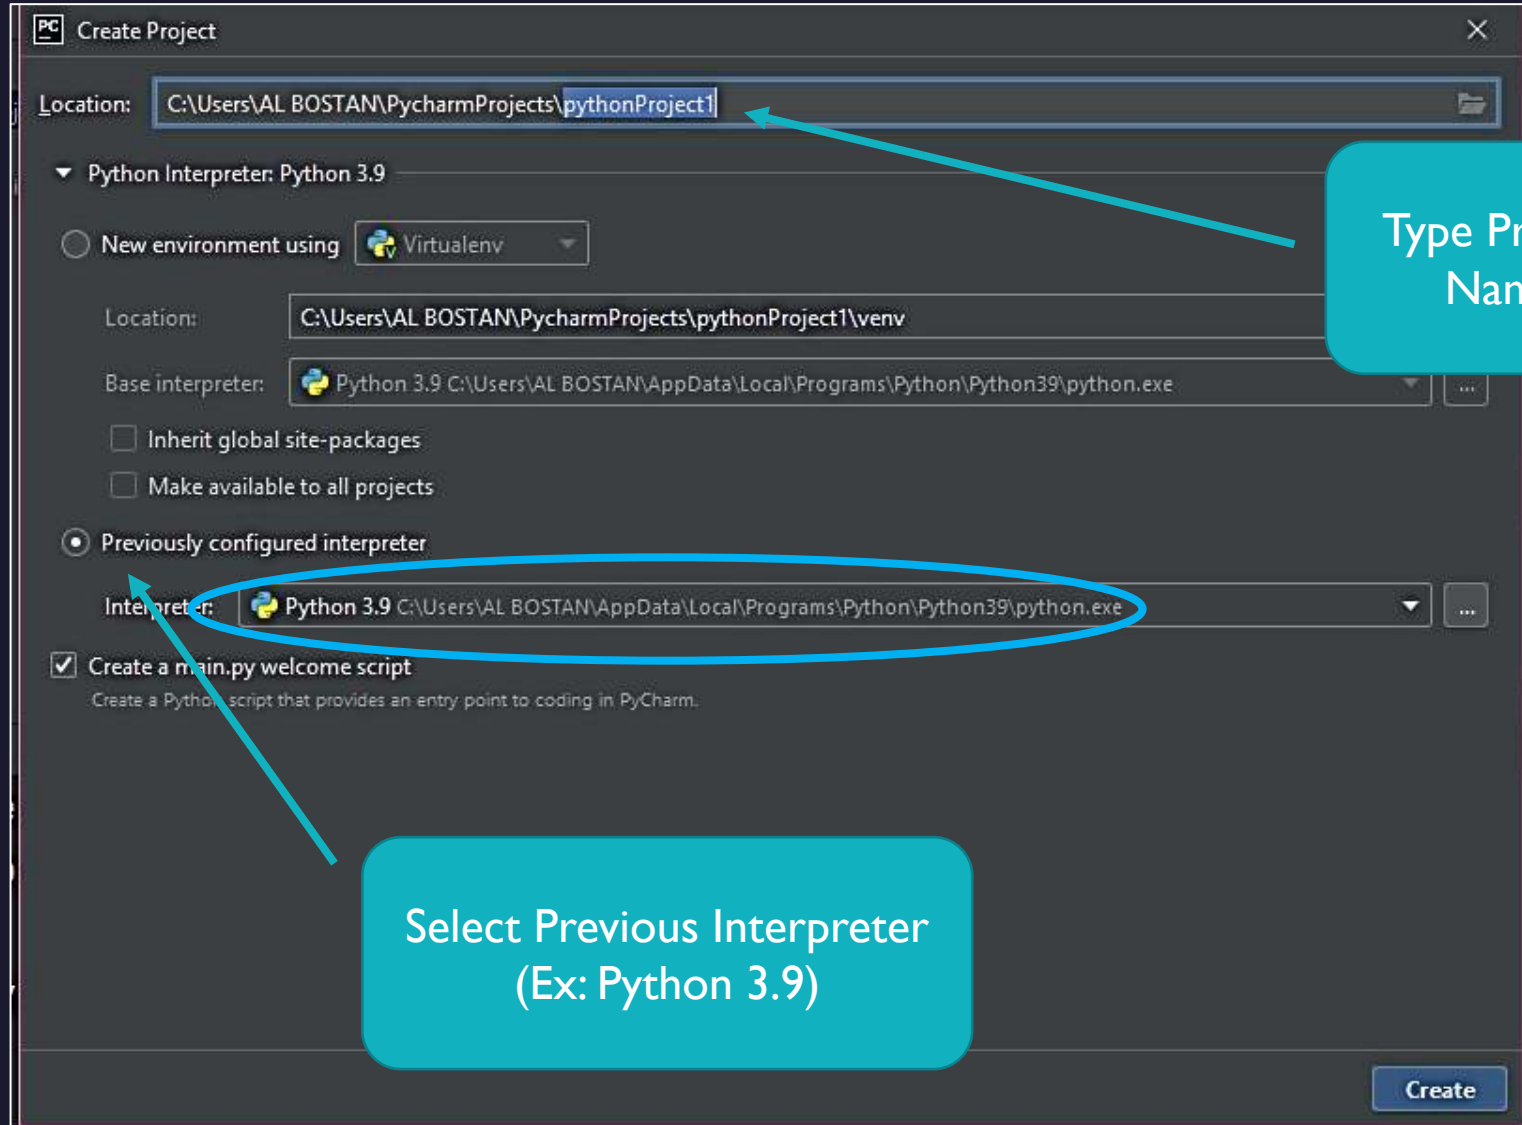

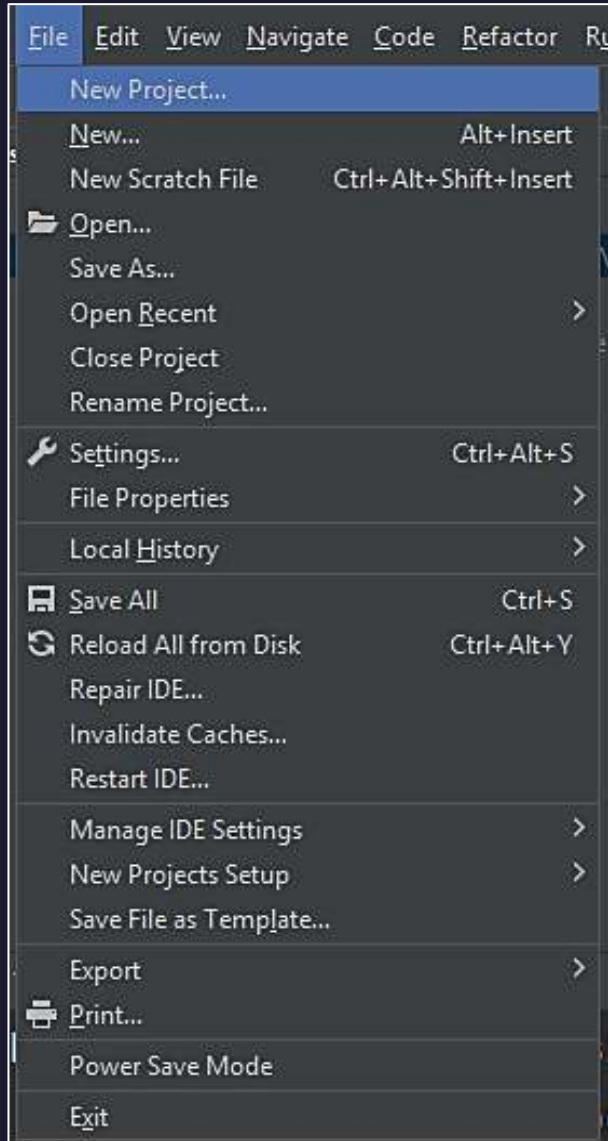

Python provides lots of libraries for image processing, including:

- **Python Imaging Library (PIL)** – To perform basic operations on images like create thumbnails, resize, rotation, convert between different file formats etc.
- Install required library

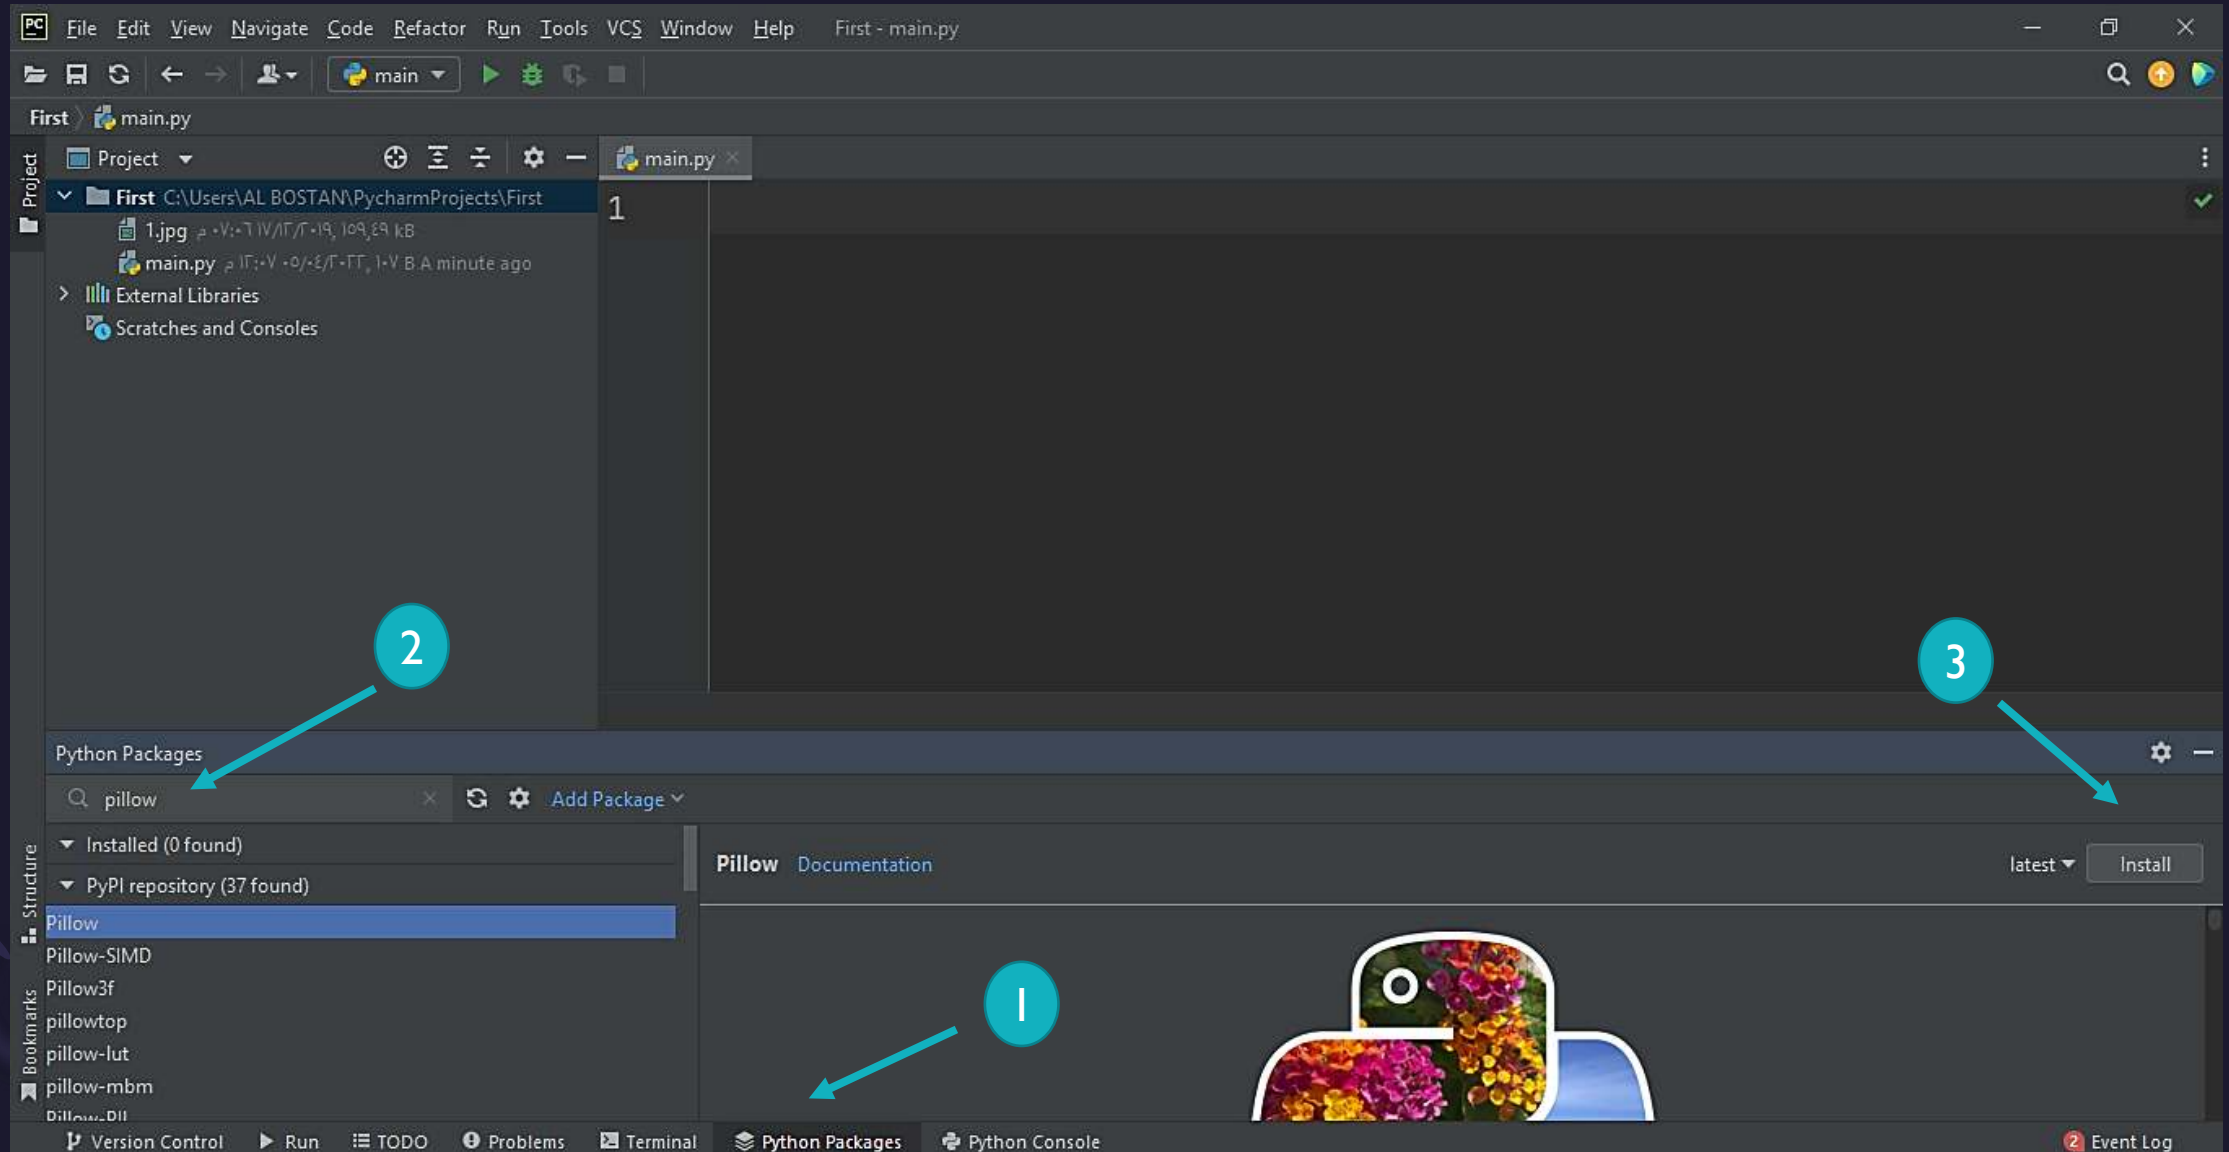

Our first step will be to install the required library, like **pillow** or other which we wants to use for image processing.

Creating New Project in Pycharm

Install Pillow

Install Pillow in vs

The screenshot shows the Visual Studio Code interface with the Python Image Preview extension installed. A red circle and arrow highlight the extension in the left sidebar. The main panel displays the extension's details, including its name, version, author, and dependencies.

Numpy, Pillow, OpenCV, Matplotlib, Plotly, ImageIO, Scikit Image, Tensorflow, Pytorch Image Preview
Disable Uninstall

This extension is enabled globally.

Python Image Preview

You can quickly check your Python image data.

Dependencies

Requires one or more of the following libraries:

- pillow
- opencv-python
- matplotlib
- image
- plotly + kaleido

Supported Libraries

Categories

- Debuggers
- Data Science
- Machine Learning
- Visualization

Install **Pillow** in vs

```
python -m pip install pillow
```

Image: Open() and show()

Output

```
#Import required library  
from PIL import Image  
  
#Open Image  
im = Image.open("1.jpg")  
  
#Image rotate & show  
im.rotate(45).show()
```

Image.size: It returns the tuple consist of height & weight of the image.

Image.format: It returns file format of the image file like 'JPEG', 'BMP', 'PNG', etc.

```
print(im.size)

print(im.format)
```

Output:

```
(1600, 1066)
JPEG
```

Image.width: It returns only the width of the image.

```
print(im.width)

1600
```

Image.height: It returns only the height of the image.

```
print(im.height)

1066
```

Image.info: It returns a dictionary holding data associated with the image

```
print(im.info)

{'jfif': 257, 'jfif_version': (1, 1), 'dpi': (96, 96),
'jfif_unit': 1, 'jfif_density': (96, 96)}
```

Image.filename: This function is used to get the file name or the path of the image.

```
print(im.filename)
```

```
1.jpg
```

Image.mode: It is used to get the pixel format used by the image. Typical values are “L”, “L”, “RGB” or “CMYK”..

```
print(im.mode)
```

```
RGB
```

Convert and Save() Image

We can change the format of image from one form to another:

```
im.save("1.png")
```

Resize the image

The `resize()` function doesn't modify the used image. Instead, it returns another Image with the new dimensions. The `Image.resize()` method returns a resized copy of the source image.

```
resized_img = im.resize((300,300))  
print(resized_img.size)    #(300,300)  
resized_img.show()
```

Resize-thumbnails()

We can change the size of image using `thumbnail()` method of pillow –

```
im.thumbnail((300,300))  
  
im.save('image_thumbnail.jpg')  
  
im2 = Image.open('image_thumbnail.jpg')  
  
im2.show()  
  
print(im.size)      #(300,200)
```

Difference between `resize()` vs. `thumbnail()`

- The `resize()` method returns the image whose width and height exactly match the passed in value.

This could be what you want, but at times you may find that the images returned by the `resize()` function aren't ideal. This is mostly because the method doesn't account for the image's Aspect Ratio, so you might end up with the image that either looks stretched or squished.

- If you want to resize the image and keep their aspect ratios as it is, then you should use a `thumbnail()` function to resize them

Converting to grayscale image – **convert()**

We can make the grayscale image from our original colored image.

```
im_gray = im.convert('L')  
im_gray.show()
```

Where "L" stands for 'luminous'.

Merging two images

In the same way, to merge two different images, you need to:

- Create image object for the required images using the **open()** function.
- While merging two images, you need to make sure that both images are of same size. Therefore, get each sizes of both images and if required, **resize** them accordingly.
- Create an empty image using the **Image.new()** function.
- Paste the images using the **paste()** function.
- Save and display the resultant image using the **save()** and **show()** functions

```
from PIL import Image

image1 = Image.open("elephant.png")

image1.show()

print("Size of image 1: ", image1.size)

image2 = Image.open("mountain.png")

image2.show()

print("Size of image 2: ", image2.size)

# Resize first image

image1 = image1.resize((image2.width, image2.height))

image1_size = image1.size

image2_size = image2.size
```

```
new_image =  
Image.new('RGB', (2*image1_size[0], image1_size[1]), (250, 250, 250))  
new_image.paste(image1, (0, 0))  
new_image.paste(image2, (image1_size[0], 0))  
new_image.save("Merged_image.PNG")  
new_image.show()
```

Input image 1:

Input image 2:

Merged Image

Task

Write python program that convert RGB image to Binary and save it as 'png'.

Thank You
